

Synthetic Study of Reproducible Document Processing

Alice Example and Ben Sample

Department of Computer Science, Example University

October 2026

Abstract

We describe a benign synthetic study of reproducible document processing.

This fixture checks retained scholarly structure and page coordinates.

1 Introduction

Document processing requires explicit provenance and preserved originals.

Example and Sample (2024) describe a controlled validation procedure.

The present study measures a local CPU service with no metadata lookup.

2 Methods

We generated two pages containing a title, abstract, methods and references.

All paragraphs and reference records were written for this software test.

The original bytes remain unchanged during repeated structured extraction.

3 Results

The experiment reports cold and warm service request times separately.

A successful request is not a claim of exhaustive text or citation accuracy.

The CPU runtime returns page surfaces and region coordinates in raw TEI.

4 Discussion

Learned extraction can omit or misclassify synthetic scholarly fields.

Raw evidence is retained so that downstream projections can be audited.
